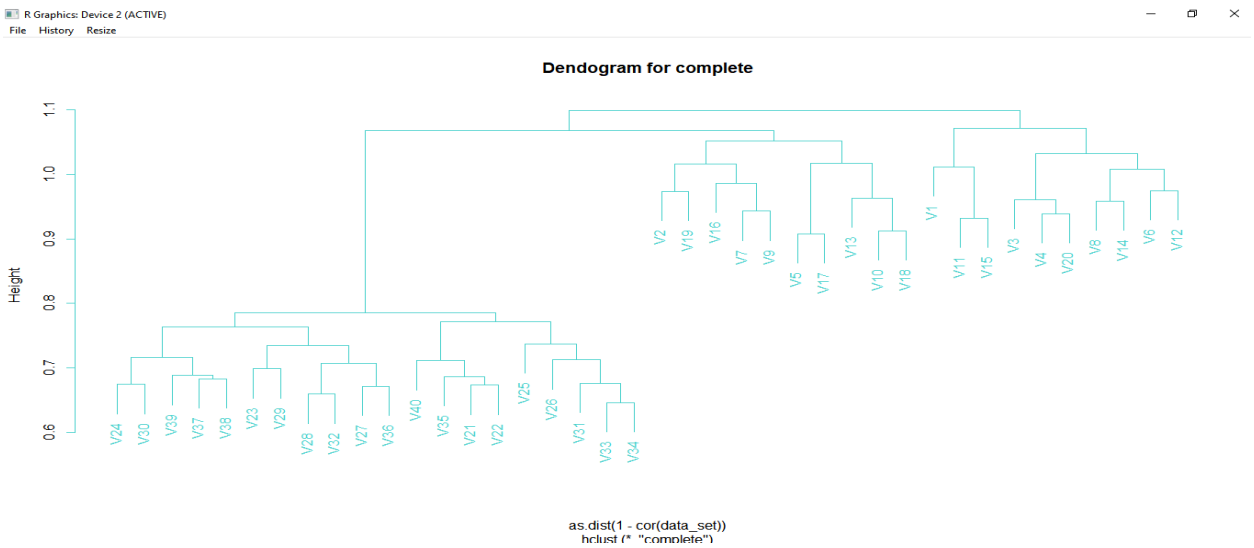
Question 2:

a)

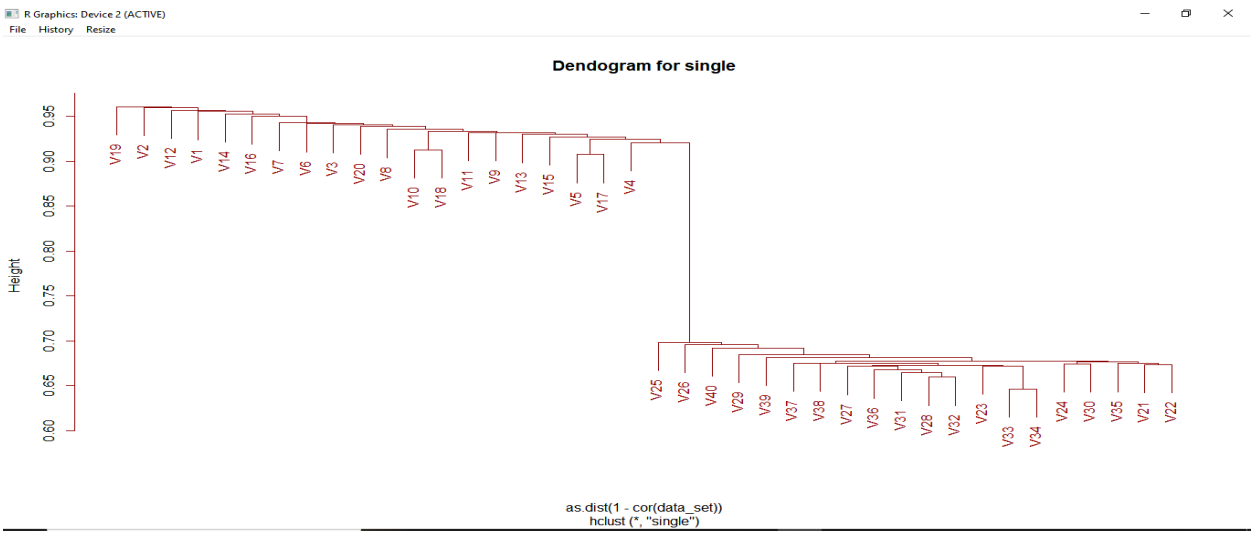
```
> data_set = read.csv("C:/shreyas/document/books/statistical_data_mining/Ch10Ex11.csv", header = FALSE)
>
```

b) Hierarchical clustering using correlation based distance.

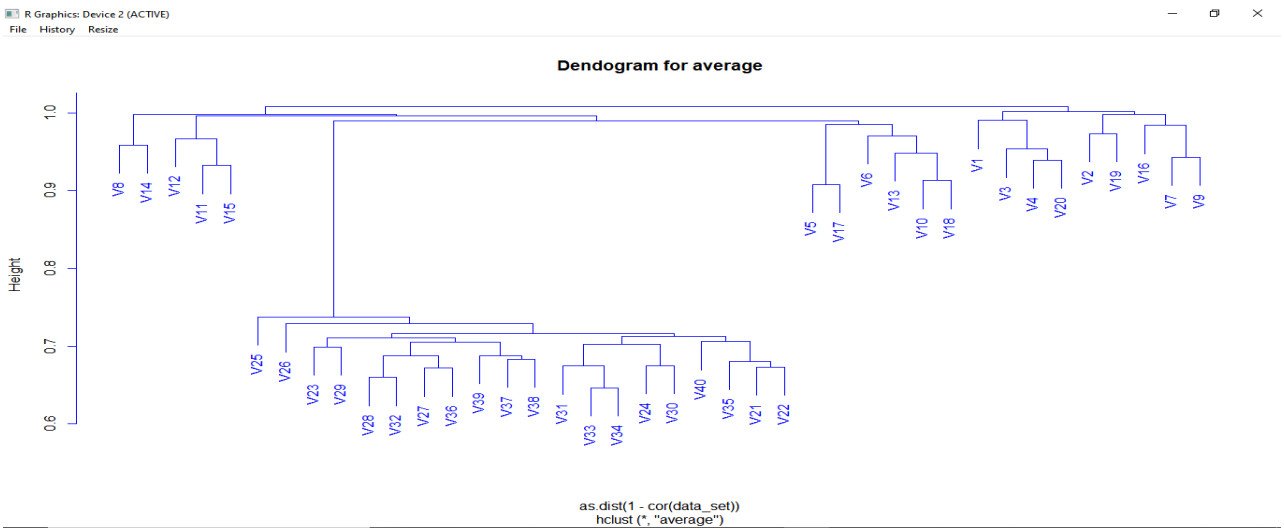
Dendogram for complete linkage



Dendogram of single linkage



Dendogram for Average Linkage



Dendogram for centroid Linkage

- Yes the result does depend on the type linkage used for clustering. In the above case, We got two clusters for complete and single linkage and three clusters for average linkage. Therefore , the result depends upon the type of linkage used.

c)

- There fore when tried with K-means as follows:

```
> kmean =  kmeans(t(data_set), centers=2)
> kmean$cluster
 V1  V2  V3  V4  V5  V6  V7  V8  V9 V10 V11 V12 V13 V14 V15 V16 V17 V18 V19 V20 V21 V22 V23 V24 V25 V26 V
27 V28 V29
  2   2   2   2   2   2   2   2   2   2   2   2   2   2   2   2   2   2   2   2   1   1   1   1   1   1
 1   1   1
V30 V31 V32 V33 V34 V35 V36 V37 V38 V39 V40
  1   1   1   1   1   1   1   1   1   1   1
```

- K-means seperates the data into two different groups as shown above.

Running K-means with 2 clusters for different expression values.

```
> kmean2 <- kmeans(data_set, centers=2, nstart=20)
> kmean2$cluster
   [1] 2 2 2 2 2 2 2 2 2 2 1 1 1 1 1 1 1 1 1 1 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2

```

- The K-means with 2 clusters result shows that the genes 11-20 and 501-600 differ most between 2 groups as shown above figure.
